Our Report, Explained Simply

A reading guide to "What Missionary Control Left in the Language of Two 1880s isiXhosa Newspapers"

Companion notes for E. Azubuike, G. Ayensu and B. Mkhize (not for submission)

10 Questions a marker might ask (with short answers) 6

1 The whole report in five sentences

1. Two isiXhosa newspapers ran side by side in 1884–88: *Isigidimi*, controlled by missionaries, and *Imvo*, owned by Africans.
2. We asked: did missionary control change *what* the papers wrote about, or also *how* they wrote about it?
3. **What** they wrote about clearly differs: Imvo talks about parliament about 3.3 times as much; Isigidimi talks about religion about 4 times as much. The religion gap appears in **readers' letters** too, so it comes from who wrote to each paper, not only from the editors.
4. **How** they wrote is much harder to see: there are hints that Isigidimi used political words in a more religious way, but this rests on one word, *umhlaba*, which the two papers use in different senses ("the earth" versus "land under law"), and a neutral control word shows the same pattern, so we cannot claim it.
5. Separately, modern AI tokenizers find this old text more expensive to process, and the African-language model is hit hardest by the old spelling, which is a fairness issue.

2 The setting: why these two newspapers?

- **Isigidimi sama-Xosa** (1870–88) was run from the Lovedale mission. Its content was under missionary control.
- **Imvo Zabantsundu** was founded in November 1884 by J. T. Jabavu, who had edited Isigidimi. It was the first African-*owned* isiXhosa paper, free "from any missionary control".
- From November 1884 to 1888 *both* papers had African editors (Gqoba at Isigidimi, Jabavu at Imvo). So the real difference between them is **ownership**/**control**, not the editor's race. This is why the comparison is meaningful.
- The texts come from the IsiXhosa Intellectual Traditions digital archive (Schoots et al., 2023a). They were transcribed and corrected by people, but not spell-checked.

3 The two big ideas: agenda versus framing

These come from communication research and are the backbone of the report.

	Agenda-setting (McCombs & Shaw)	**Framing** (Entman)
Question	*What* does the paper talk about?	*How* does it talk about it?
Everyday example	One paper prints many parliament stories, the other prints few.	Both mention "land", but one talks about it like a gift from God, the other like a legal right.
How we measure it	**Salience**: how often a topic's words appear (per million words).	**Embeddings**: which other words a word tends to appear near.

In plain words: "Agenda" is about counting topics; "framing" is about the company words keep. Our main finding is that the agenda difference is clear and the framing difference is not.

4 Our three hypotheses

H1 (agenda) The papers differ in how often they use political and religious vocabulary.

H2 (framing) They differ in how they use political words, with Isigidimi's political words sitting closer to religious language.

H3 (fairness) Modern tokenizers charge more to process this historical text and its spelling.

5 Glossary: every technical term in the report

Term	**What it means**
Date-matched sample	Imvo has far more text (1.31M words) than Isigidimi (287k). For each month, we pick just enough Imvo pages to match Isigidimi's size, ten times over. So we compare like with like, same months, same amount of text.
Stem	The core of a word, e.g. *palamente* (parliament). isiXhosa adds prefixes and suffixes, so we count every word containing the stem.
Rate ratio	How many times more often Imvo uses a topic than Isigidimi. 3.3 = Imvo uses it 3.3$\times$ as often; 0.24 = Imvo uses it about a quarter as often (so Isigidimi about 4$\times$).

Term	What it means
CI (confidence interval)	The plausible range for a number, given random variation. If a ratio's CI includes 1, the papers might not really differ.
Matched sets	Our fairness check. We build 2000 random groups of words with the same total frequency as the topic, and ask: does the real topic differ more than these random groups? If it beats 95% of them, $p < 0.05$.
p-value	The chance of seeing a difference this big if there were really no difference. Small = surprising = evidence.
Bonferroni correction	If you run 15 tests, some will look "significant" by luck. Bonferroni makes the bar stricter: $0.05/15 \approx 0.003$.
Era drift	How much a topic's rate changes *within one paper* between earlier and later years. If a paper changes a lot over time on its own, a difference between papers might just be about timing.
Readers' letters	Pieces sent in by readers. They open by addressing the editor (*nkosi mhleli*, "sir, editor") and close with a signature. Comparing letters with the rest of each paper tells us whether a difference comes from the editors' own writing or from the people who wrote in.
Word sense	One word can carry different meanings. *Umhlaba* can mean "the earth/world" or "land" (as property). If two papers use different senses, an embedding model will place the word differently even if neither paper "frames" land differently.
Classifier	A model trained to guess which paper an issue came from. It got 83% balanced accuracy and pointed us to religious words, but it was trained on the same years we test, so the religion result is labelled *exploratory*.
Word embedding	A list of numbers for each word, learned from which words appear near it. Words used in similar contexts get similar numbers. We used fastText.
Window	How many neighbouring words count as "context". Window 1 = only the immediate neighbours (captures grammar); window 5 = a wider neighbourhood (more topic).
Seed stability	Train the model twice with different random starts; do the words get the same nearest neighbours? fastText scored 0.83, word2vec 0.64, so we used fastText.
Profile shift	For one word, compare its similarity to 500 common words in Isigidimi's model versus Imvo's model. 0 = used identically; higher = used differently. Captures a word's *overall position*.
Jaccard (neighbour overlap)	Compare a word's 10 nearest neighbours in each paper. Captures a word's *immediate company*.
Permutation null	Shuffle issues between the two papers and measure shift again. This tells us how much shift appears by chance alone.
Global gap	Real shift (0.348) minus chance shift (0.230) = 0.118. The papers' language differs overall, beyond chance.
Directional test (Δ)	For political words: are they closer to religious words or political words? $\Delta > 0$ means "more religious in Isigidimi than in Imvo". Measured in z-score units (standard deviations).
Anchors	The reference words for "religious" (e.g. *yesu*, *izono*) and "political" (e.g. *wonyulo*, *endlu*), chosen from other years before testing (Table S4).
Neutral control	Words that should *not* differ (time, house, rain, cattle). If they "differ" as much as political words, the political result is not specific.
Detection floor	The smallest shift our test could reliably notice. For a one-word concept it is 0.15, bigger than the whole global gap (0.118). So small framing differences would be invisible to us.
Tokenizer	The first step of a language model: chopping text into pieces (subwords). More pieces = more cost and usually worse performance.
Fertility / cost	Subwords per word (or per character). Higher = more expensive.
Aspiration marks	Modern isiXhosa writes *th, kh, ph*; 1880s spelling often wrote *t, k, p*. We stripped the *h* from modern text to imitate old spelling.

Term	What it means
Per word vs per character	Spelling-only test: same words, so compare per word. Historical text: word division differs, so compare per character.

6 What we did, step by step

1. **Prepare the data**: take the isiXhosa text of both papers, Nov 1884 to 1888; build ten size-matched Imvo samples.
2. **Salience (H1)**: count topic words per million; compare with ratios, confidence intervals and the 2000 matched sets; check era drift using other years (Isigidimi 1876–83, Imvo 1889–94).
3. **Framing (H2)**: train fastText on each paper; measure profile shift and Jaccard for each topic; compare against the shuffled null and matched sets; run the directional (religious vs political) test; repeat in five settings (window 1, 2, 5, and with run-together words joined) to see whether results hold up.
4. **Letters (H1, how control worked)**: split each page into readers' letters (they start by addressing the editor, "nkosi mhleli ... kaundifakele" = "sir, editor ... please print", and end with a signature) and everything else; compare religion and parliament in each part. We checked 30 random detected letters by hand: 28 were real letters.
5. **Senses of umhlaba (H2)**: for every use of *umhlaba*, look at the 10 words around it and count religious words (heaven, God, Christ) and property/political words (title deed, law, government).
6. **Tokenizers (H3)**: run three models (XLM-R, mBERT, Serengeti) on modern isiXhosa news, on the same news with old-style spelling, and on our historical text; compare costs.

7 What we found, and what each number means

H1: Agenda (supported, with care)

- Imvo uses parliamentary words **3.3**$\times$ as often ($p = 0.018$ against matched sets).
- Isigidimi uses religious words about **4**$\times$ as often (ratio 0.24, $p = 0.020$).
- Neither passes the strict Bonferroni bar ($p < 0.003$). So we do not rest on p-values alone; we rest on two other supports:
  - *Corroboration*: the religion gap matches what the archive's own authors wrote ("church and Bible stories").
  - *Robustness*: the religion gap is larger than era drift.
- Caution for parliament: Isigidimi's parliament rate drifts 1.8$\times$ between eras (CI up to 5.0), which overlaps the 3.3$\times$ gap. So parliament is less secure than religion.
- *Vote* and *government* change a lot over time within a paper, so we do not interpret them.
- **Letters**: readers who wrote to Isigidimi used religious words 3$\times$ as often as Imvo's letter-writers (ratio 0.33, CI 0.17–0.65); in the rest of each paper the ratio is 0.22. Parliament is too rare in Isigidimi's letters (2 uses) to judge.

In plain words: The papers clearly printed different things. Religion is the strongest, best-supported difference, and it is not just the editors: the two papers had different communities of writers (or chose different letters to print).

H2: Framing (weak, not specific)

- Overall, the two papers' word usage differs beyond chance (global gap 0.118).
- But **no single topic** stands out: parliament reaches the 96th percentile, yet the neutral word *cattle* reaches the 90th–99th.
- Parliament + vote together: neighbours (Jaccard) differ in 3 of 5 settings; overall position (profile) differs in only 1. So the *immediate company* of political words changes, but their *overall position* barely does.
- The directional test: political words lean towards religious words in Isigidimi in all 5 settings and pass Bonferroni in 3. **But**:
  - it mostly depends on one word, *land* (*umhlaba*, which can also mean "earth/world", a religious-sounding meaning);
  - the neutral control *house* leans even further (Δ +0.84 to +1.51), possibly because *endlu* ("in the house") is one of the political anchors;
  - *umhlaba* sits near religious words in 3.4% of Isigidimi's uses but 0.9% of Imvo's, and near property/political words in 13% versus 27%. So the "lean" is probably a difference in *which meaning* each paper uses, not a different slant on the same idea.
- The detection floor (0.15) is larger than the global gap, so small framing differences cannot be ruled out, only large ones.

In plain words: There are hints that Isigidimi wrote about politics in more religious terms, but our own controls show similar patterns, so it is a lead for future work, not a finding.

H3: Tokenizers (supported)

- Historical text costs more for every model: Serengeti +12.4%, XLM-R +4.1%, mBERT +1.7% (per character).
- Old spelling alone raises cost only for **Serengeti**, the African-language model (+2.2% per word); for XLM-R and mBERT it actually lowers it.
- A likely reason: Serengeti's vocabulary has twice as many pieces containing *th/kh/ph* (1.9% vs 0.9%), so it is tuned to modern spelling. This is a hypothesis from one model.

In plain words: The model built for African languages is the one most penalised by historical African-language text.

8 How to read the figures

Figure 1, left Each dot is a topic. Right of the dashed line = more in Imvo; left = more in Isigidimi. Filled dots beat the matched sets at $p < 0.05$. Look for parliament (far right) and religion (far left).

Figure 1, right Each row compares the two papers on one topic in one part of the paper. Blue dot = Isigidimi, orange = Imvo; the number on the right is the Imvo/Isigidimi ratio. Religion: blue is to the right (more religious) in both letters and the rest. Parliament: orange is to the right in both, but Isigidimi's letters have only 2 uses.

Figure 2(a) Religious words in Isigidimi were already falling from 1876, long before Imvo existed. So Imvo's arrival did not *cause* the religion gap.

Figure 2(b) How often *umhlaba* appears near religious words (top) or near title/law/government words (bottom), in each paper. Isigidimi leans to the religious sense, Imvo to the legal/political sense.

Figure 2(c) Cost compared with modern text. Left group: spelling only (only Serengeti goes up). Right group: real historical text (all go up, Serengeti most).

9 The Discussion, simplified

1. **Answer**: the papers differ clearly in what they printed, as missionary control would predict. Whether control also changed *how* contributors wrote, our data cannot show.
2. **Not causal**: religious language was already declining before Imvo, and the parliament rise coincides with an editor, a publication change and an election, which we cannot separate.
3. **How control worked**: the religion gap is in readers' letters as well as the rest, so the two papers had different contributors (chosen by editors or by writers' own choice of paper; print cannot tell which).
4. **Why framing is hard**: narrow windows mainly capture grammar; the lean depends on one word; a control word behaves the same.
5. **Responsible NLP**: tokenizers penalise this text, especially for the African-language model; "fixing" old spelling would erase the very history the archive preserves (and cannot be reversed: old *t* could be modern *t* or *th*); interpreting these patterns as cultural claims without isiXhosa speakers would be extractive (Bird, 2020).
6. **Limitations**: only two papers, one time window, a missing year (1886), no editor metadata, a modern-news domain mismatch, and stems/glosses not yet reviewed by a speaker.

10 Questions a marker might ask (with short answers)

Why not just compare all years? Imvo only exists from Nov 1884; comparing different years would mix up "which paper" with "which era".

Why not trust p-values alone? With many tests some will pass by luck; we use matched sets, era drift and the archive's own account instead.

Why is framing weak if the papers clearly differ? About 300k words per paper is small for embeddings; our detection floor is above the overall gap.

Why include neutral controls? To check that "political" results are not just general differences between the papers. *House* showed they partly are.

What is new compared with Schoots (2023b)? He counted root words over time; we add matched baselines, a date-matched design, an embedding framing test, a letters-versus-rest test of how control worked, and a tokenizer fairness audit.

How do you find letters? By their opening: they address the editor directly (*nkosi mhleli*, "sir, editor") and ask to be printed (*kaundifakele*); third-person mentions (*u mhleli*, "the editor") are excluded. A hand check found 28 of 30 detections were real letters.

Why move two plots to the supplement? The framing-percentile and parliament-by-year plots are still in the supplement (Figs S1–S2); the new plots answer the research question more directly.

Is this responsible? We describe the papers, not isiXhosa people, and flag that a first-language speaker must review the word lists before any cultural claim.
